

Application Note

Predicted Normal Values Overview

C. Buess, June 2025

This document describes in detail which predicted normal values are implemented in ndd's products. For each publication, it lists the available predicted and lower limit of normal values, indicates the applicable age ranges, and describes special features such as ethnic correction.

1. Description of Tables for Predicted Values

The two tables of predicted values, shown at the end of this document, contain the following items:

Reference Name:	The reference name is used in the spirometry device or its software. The name consists of the main author of the study, optionally the study name or country in parentheses, and the latest year of publication.
Abbreviation:	Abbreviation for the study. In the tables, the abbreviation is used if parameters from another study are applied. Example: For most studies, 'Cherniak' (abbreviation CH) predicted values are used for the MVV parameter.
Age Range:	Age range used by the study. If the age range was extended beyond the study's range, the extended range is shown in parentheses.
Height Range:	Height range used by the study. Extended range is also listed in parentheses.
Use of Weight:	Specifies whether the patient's weight is used in the equations for the predicted values.
Ethnicity:	Ethnic groups that are supported by the study. A green field marked with 'o' means that the value is directly supported by the study. A green field without 'o' means that the predicted values are computed by the software using ethnic correction values.
Parameter:	In the parameter list, the following indicators are used: <ul style="list-style-type: none"> o The parameter is available in the study. FVC, IVC If 'FVC' is indicated in the field for VC, the study's FVC value is used for its parameter VC. FEV1/FVC FEV1/FVC is computed from the predicted values of FEV1 and FVC of the same source. x FEV1/FVC is used for FEV1/VC (or vice versa). AB The value is taken from the predicted source with the abbreviation AB.
LLN of Parameter:	This table lists the lower limits of normal (LLN) provided by the study. Most modern publications, e.g., those provided by GLI, use separate equations for LLN. If the lower limit of normal values are not available as an equation, they are computed using the following formula: LLN = PredictedValue - 1.645 × SEE (Standard Error of Estimate). If there is no SEE value, the LLN is set to 80% of the predicted value for absolute parameters (FVC, FEV1, etc.) and to 90% of the predicted value for relative parameters such as FEV1/FVC.

Application Note

There are two cases where an upper limit of normal (ULN) is listed in the LLN column of a report: 1) For the parameter LCI, and 2) for the parameter RV/TLC when using the predicted source Vazquez-Garcia (ALT), 2016.

Lung Age: Lung age is based on the measured FEV1 value of a patient. Using the predicted value equation for FEV1, lung age is determined by solving the equation for age: The input variables are the patient's demographics (gender, height) and the measured FEV1 value. The output variable constitutes the patient's lung age. Lung age, therefore, is the age at which the measured and the predicted FEV1 value of a patient are equal. The computation is based on the following publication: Spirometric Lung Age Estimation for Motivating Smoking Cessation. J.F. Morris, W. Temple. Prev Med 14, 655-662 (1985).

2. Extended Predicted Value Range

Published predicted spirometry values are based on a 'normal' population. In the publications, 'normal' values for spirometry parameters are derived from all the collected measurements. These 'normal' values can usually be computed using mathematical formulas. The formulas consider a patient's gender, age, height, and in some cases ethnicity and/or weight. The application of the studies' formulas is usually limited to the age and height ranges present in the 'normal' population of that study. When the caution message 'Extended predicted range used' is displayed on the device, this indicates that the formulas of the publication are being used, but the patient's age and/or height are above or below those of the 'normal' population that was used for the particular study. The formulas have been verified by ndd to be stable in the extrapolated range.

3. Additional Pediatric Predicted Values

The software allows specifying additional pediatric predicted values (separately for spirometry and for DLCO & lung volumes). If additional pediatric values are specified, then these values take precedence over the main predicted values.

Example: Spirometry predicted is set to 'Quanjer (GLI), 2012' and additional spirometry predicted is set to 'Zapletal, 1977'. The 'Zapletal 1977' predicted values have an age range of 4 to 17 years. If a test is performed with a 6-year-old patient, then the 'Zapletal 1977' values are used. If a test is performed with a 18-year-old patient, then the 'Quanjer (GLI), 2012' values are used.

4. Ethnic Correction

Ethnic correction factors are only applied if the study does not directly support the selected ethnic group (see predicted overview table). The following two examples are used for clarification:

1. NHANES-III provides equations for predicted values for the ethnic groups Caucasian, African, and Hispanic. Ethnic correction factors defined in the software are therefore only used for the ethnic groups Asian and Other.
2. ERS predicted values only provide predicted values equations for the ethnic group Caucasian. In this case ethnic correction factors are used for all other ethnic groups.

The use of ethnic correction factors is always indicated on the report and in the software in the following way: NHANES-III × C, where C is the applied correction factor.

The following table lists which predicted values are affected by the ethnic correction factor:

Application Note

Applied Correction	Predicted Value and LLN of Parameter
Multiplication by factor C	FVC, FIVC, FEV1, FEV3, FEV6, VC, FEV0.75, FEV0.5, MVV, VA, TLC, RV, IC, FRC
No correction	FEV1/FVC, FEV1/VC, FEV0.75/FVC, FEV0.5/FVC, FEV3/FVC, FEV1/FEV6, FEF25, FEF50, FEF75, FEF2575, PEF, PIF, MIF, DLCO, DLadj, DLCO/VA, RV/TLC, LCI

Note: Neither DLCO nor DLCO/VA are adapted using ethnic correction factors. The population data suggests that no ethnic correction is required for DLCO. Since the DLCO parameter is calculated from a VA derived from the tracer gas dilution, and VA directly effects DLCO in the calculation, any alteration in VA would also alter DLCO and DLCO/VA. Thus, in the predicted DLCO values, we need to predict DLCO to 'match' as closely to the normal/healthy populations as possible. Neither DLCO nor DLCO/VA require any ethnic correction.

5. Remarks Regarding Predicted Normal Values for Diffusion Capacity & Lung Volumes

1. The article by B. Make et al. compares different sources for predicted normal values and concludes that "the same subject may be classified as 'normal', 'abnormal' or 'very abnormal' depending on which equation is used". This specifically applies to the predicted sources published by B. Burrows (very low values) and Ayers (no age dependency). See Make B, Miller A, Epler G, Gee JBL. Single breath diffusing capacity in the industrial setting. Chest 1982;82(3):351–356.
2. H.I. Goldman and M.R. Becklake's predicted values are only used for TLCsb, RVsb, RV/TLCsb, and FRC.
3. Thompson et al.'s predicted values can only be applied down to the age of 45 years (see publication). In cooperation with the authors, it was decided to combine the predicted values published by Thompson with those of Miller for ages <45 years in ndd's software.
4. VA and/or DLCO/VA predicted values are computed assuming $VA = TLC_{sb} - V_d$, where V_d represents the anatomic dead space. Alternatively, TLCsb is computed by adding V_d to VA.
5. DLCO predicted values by Vazquez Garcia et al. (ALAT 2016) depend on the 'altitude of residence' of the patient. The appropriate value must be entered in the patient's record stored on the device.
6. ERV predicted is computed by subtracting RV predicted from FRC predicted, if both RV and FRC predicted originate from the same source.
7. IC predicted is computed by subtracting FRC predicted from TLC predicted, if both FRC and TLC predicted originate from the same source.
8. Predicted values are taken from Hall et al. (Ha21, GLI reference values for static lung volumes).
9. The Predicted source Vazquez-Garcia (ALAT), 2016 determines an upper limit of normal (ULN) and not a lower limit of normal (LLN) for the parameter RV/TLC.
